Project Title: FERTILITY ASSESSMENT AND INVESTIGATION MANAGEMENT SYSTEM USING PYTHON OOP

Name: Nuwarinda Roseline

Course: MSc Data science and Analytics

Student Number: S26M19/017

Access Number: B38638

Submission date: 12th October 2026

1. Background and Problem Statement

Fertility assessment may involve several consultations and investigations, including reproductive history, laboratory tests, imaging and assessment of the male partner. The American Society for Reproductive Medicine recommends a systematic evaluation to identify factors that may affect conception [1]. However, when records are maintained across different visits, missing results and poorly documented follow-ups can make it difficult to track completed and pending investigations, potentially delaying clinical review, diagnosis and management [2].

This project will develop a Python-based **Fertility Assessment and Investigation Management System** to organize patient profiles, consultations and investigations. It will validate records, flag missing results, track follow-ups and generate assessment summaries. The system will support record management and clinical review but will not diagnose infertility or recommend treatment.

2. Aim and Objectives

Aim: To develop and test an object-oriented Python application for managing fertility assessment records.

Objectives:

1. Develop classes for patient profiles, consultations, investigations and assessments.
2. Implement object relationships and demonstrate encapsulation, inheritance, polymorphism and abstraction.
3. Develop validation checks for missing results, duplicate records, invalid dates and inconsistent statuses.

4. Create an interface for viewing investigation progress, outstanding follow-ups and assessment summaries.
5. Test the application using fictional records and predefined test cases.

3. System Design and OOP Implementation

The application will use Python for core functionality, SQLite for data storage and Streamlit for the user interface. Pandas may support data processing.

The main classes will include **Woman**, **FertilityAssessment**, **AssessmentRecord**, **Investigation**, **Appointment**, **DataQualityChecker** and **ReportGenerator**. Investigation and Appointment will inherit shared attributes and methods from the abstract AssessmentRecord class while implementing their own summary methods. This will demonstrate inheritance and polymorphism. Encapsulation will be applied through controlled methods for creating and updating records, while abstraction will separate shared record behaviour from specific implementation details.

The system will link each patient to the relevant assessment, consultations and investigations. It will validate entered information, identify missing or inconsistent records, and generate summaries of investigation status and outstanding follow-ups. Exception handling will help manage invalid inputs and database errors.

4. Scope, Methodology and Testing

Development will follow an incremental approach over three weeks. The system will use approximately 50 fictional records representing different consultation histories, investigation statuses and data-quality issues. No real patient data will be used.

Testing will cover class methods, object relationships, validation rules, exception handling, database operations and report accuracy. System outputs will be compared with expected results from predefined test cases.

5. Expected Deliverables: Deliverables will include a working Python application, SQLite database, fictional dataset, modular and documented OOP code, automated tests, an interactive interface, assessment summaries and a GitHub repository containing the source code and README instructions.
